REPORT 01 / 18 OCTOBER 2026

# AI Opportunity Report

A practical AI opportunity for Cynbit Technologies, evaluated against adjacent use cases and framed as a measurable pilot.

Prepared by Suhail Kataria | 18 October 2026

## Decision in brief

Recommend the **Cynbit AI Solutions Architect** as a discovery-assistance pilot. It converts a structured business questionnaire into a reviewable solution blueprint, including feasibility, architecture, roadmap, risks and candidate KPIs. The value is earlier clarity for prospective clients and a reusable starting point for Cynbit's solution team; it is not a substitute for an architect's judgment or a quotation.

## Company context

Cynbit publicly presents AI automation, custom software and cloud systems, SaaS platforms, and digital marketing/SEO as service lines. Its services page describes autonomous agents, LLM automation, software engineering and cloud infrastructure. Its AI/ML intern role mentions chatbots, prompt engineering and document processing. These are company-stated offerings and role priorities, not independently audited delivery outcomes [1–3].

## Opportunity hypothesis

Project discovery can require repeated explanation of a client's workflow, data, constraints and success criteria before a solution can be scoped. A consistent intake and draft could reduce omissions and help a human architect focus the first conversation. Cynbit has not supplied internal funnel data, call duration or win rates; any benefit remains a hypothesis until measured in a pilot.

## What the current proof of concept demonstrates

- Three-stage discovery, review before generation, and a structured blueprint from one explicit model request [4].
- Input and output validation, conservative KPI-source checks, budget-currency handling, JSON export and saved browser results [4].
- A responsive light/dark interface and mocked automated tests in the repository; no live-business outcome has been established [4].

Evidence boundary: public Cynbit pages support the company description; repository inspection supports implementation claims. Scoring, business impact and pilot targets below are author assessments and proposals.

02 / OPPORTUNITY LANDSCAPE

# Three credible directions

The options align with Cynbit's published AI, software and marketing capabilities [1]. Each would need different data access and operational ownership.

| Opportunity | Business use | Data and delivery dependency | Primary risk |
|---|---|---|---|
| A. Guided solution blueprint | Turn early-stage intake into a consistent draft scope for architect review. | Questionnaire answers; no live customer-system connector in the PoC. | Plausible but unsupported recommendations may look authoritative. |
| B. Support knowledge assistant | Draft answers or route common client support queries. | Permissioned knowledge base, ticket history, freshness and escalation workflow. | Wrong or stale answers reaching customers. |
| C. Document intake extraction | Extract fields from forms, briefs or invoices into review queues. | Representative documents, labels, exception handling and system integration. | Privacy exposure and extraction errors. |
| D. Marketing insight assistant | Summarize campaign signals and propose experiments. | Approved analytics access, attribution rules and human review. | Confusing correlation with causal lift. |

## Why these options

B and C are directly relevant to the intern role's stated chatbot and document-processing responsibilities [3]. D fits Cynbit's marketing practice [1]. A spans Cynbit's consulting-style discovery across service lines and can be piloted without connecting to customer systems. The comparison is therefore about a sensible first experiment, not a claim that A has the largest eventual revenue potential.

## Selection principle

Choose the narrowest useful workflow with observable quality: an architect can inspect each generated section against the original questionnaire before any recommendation reaches a client. For support or document automation, more work is needed on data permissions, representative datasets and downstream error handling before a realistic pilot.

03 / PRIORITIZATION

# Scored comparison

Illustrative 1–5 scores (5 is favorable). Weighted total = value 35% + feasibility 30% + time-to-pilot 20% + risk control 15%. Scores are judgments, not measured company results.

| Candidate | Value | Feasibility | Time | Risk | Weighted / 5 |
|---|---|---|---|---|---|
| A. Blueprint | 4 | 4 | 5 | 3 | 4.05 |
| B. Support | 4 | 3 | 3 | 2 | 3.20 |
| C. Document intake | 4 | 3 | 3 | 3 | 3.35 |
| D. Marketing | 3 | 3 | 4 | 3 | 3.20 |

## Rationale and sensitivity

A ranks first because the existing proof of concept is already inspectable and requires no client integration to test. Its risk score is only 3: a polished blueprint can create false confidence. C would become more attractive if Cynbit supplied labelled documents and a real extraction owner. B could surpass A if a curated knowledge base and escalation process already existed. The ranking should be revisited after a discovery call with Cynbit.

## Where the proposed product fits

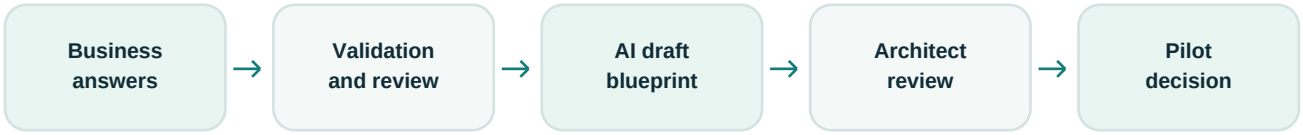

The tool supports pre-sales discovery or internal solution workshops. A business user provides context; the model drafts options; a Cynbit architect checks assumptions, budget and feasibility; only then is a client-facing scope discussed. It should not automatically promise effort, ROI, compliance or delivery dates.

## Decision gates before a real pilot

- Confirm an internal owner, consented sample briefs, and the exact point where the architect takes over.
- Define a rubric for groundedness, usefulness and critical omissions before collecting outputs.
- Agree an acceptable false-claim rate and stop criteria for sensitive or regulated sectors.

04 / PILOT DESIGN

# Workflow and measurement

## Workflow

The current application asks for industry, business description, problem, workflow, challenges, users, goals and success criteria as required fields. Optional focus-specific volumes, timeline, budget, available data, integrations and constraints add context. The user reviews answers before generating; the output separates risks, assumptions, missing information and limitations [4]. A human review stage is proposed for deployment, not implemented in this PoC.

## Pilot scorecard

| Measure | Operational definition | Proposed decision rule |
|---|---|---|
| Grounded claim rate | Share of factual or numeric claims traceable to intake or explicitly marked assumption. | ≥95% on a blinded sample; zero invented baselines in approved drafts. |
| Critical omission rate | Share of briefs missing a reviewer-defined must-have constraint or risk. | ≤10%, with zero unflagged high-severity omissions. |
| Review effort | Median architect minutes to reach a usable first-draft scope, compared with manual baseline. | Measure baseline first; seek a ≥20% reduction without lower quality. |
| User usefulness | Architect rating of actionability on a 1–5 rubric. | Median ≥4/5, with comments on failure cases. |
| Reliability | Valid, complete blueprint responses per eligible generation attempt. | ≥95% in controlled pilot conditions. |

Thresholds are proposed pilot gates, not achieved results. Compare the same briefs with and without the tool; randomize order and hide which draft is AI-assisted where feasible.

05 / LIVE DEMONSTRATION

# Proof of Concept: Successful Live Demonstration

One documented Groq request generated and rendered a blueprint for an Indian Shopify retailer selling electronics and accessories. The test brief described 800–1,200 daily support queries, a goal to automate at least 50% of routine queries, English/Hindi responses under 30 seconds, human escalation, Shopify/PostgreSQL/WhatsApp/chat/email integrations, an INR 800,000–1,200,000 budget and a 1–3 month timeline [5].

The saved result displayed five major sections: **Overview, Proposed Solution, Technical Architecture, Implementation Plan** and **Business Outcomes**. The overview states the challenge, proposed approach and target outcome; the proposed-solution view records an AI-assisted feasibility judgment [6].

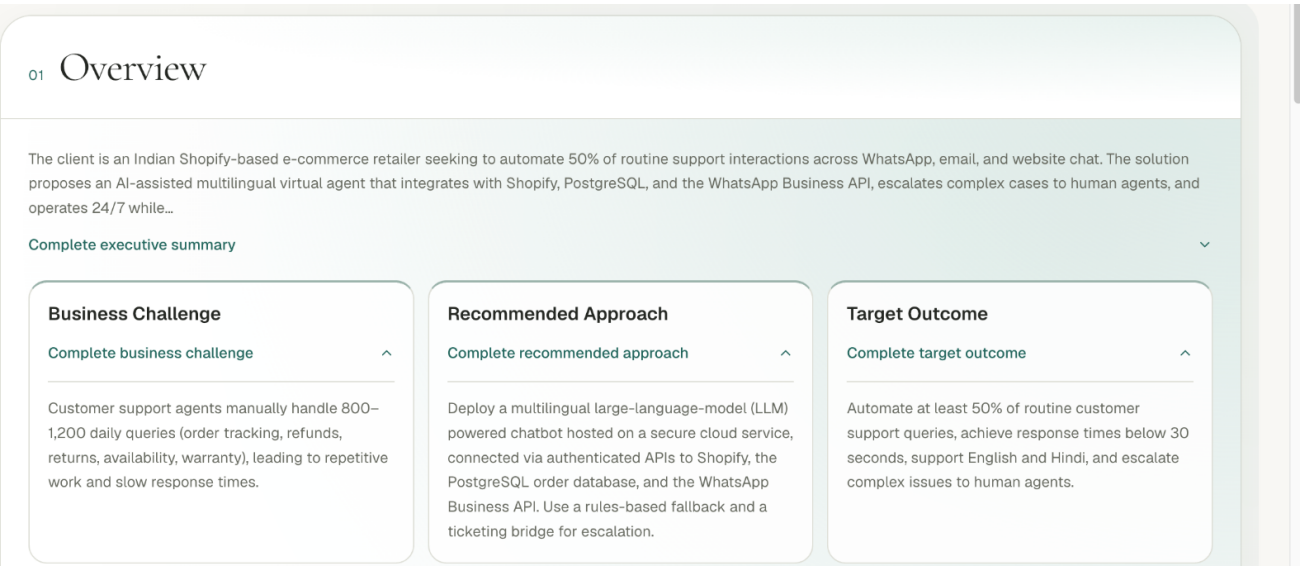

Figure 1. Overview from the successful saved blueprint. The 50% and 30-second figures are goals from the test brief, not achieved results [6a].

This demonstration supports technical feasibility of turning one reviewed intake into a structured, readable draft. It does not show that the proposed customer-support chatbot was built, that its targets were met, or that Cynbit gained measurable business value. Those claims require the unchanged pilot evaluation on page 4.

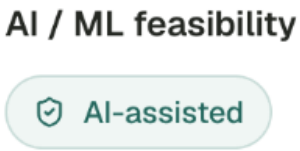

Figure 2. AI-assisted feasibility status in the Proposed Solution section of the same saved blueprint [6b].

06 / EXECUTION AND REFERENCES

# A bounded route to value

| Phase | Activity | Exit evidence |
|---|---|---|
| 1. Define | Agree use cases, rubric, privacy rules and manual baseline. | Approved 20–30 consented or synthetic briefs; reviewers calibrated. |
| 2. Evaluate | Run paired draft reviews; record errors and time. | Scorecard with intervals and a traceable failure log. |
| 3. Decide | Review false claims, effort, cost and operational fit. | Go/no-go decision and prioritized remediation. |

## Benefits and constraints

A good pilot may improve intake consistency, reduce first-draft effort and reveal missing information earlier. These benefits have not been quantified. Current limits include no authentication, no durable server-side rate limits, no customer-system integration, no retrieval or live source checking, and no evidence that generated plans are commercially or technically correct [4]. The browser stores answers and results in localStorage, so confidential material should stay out of this PoC.

## Future scope if the pilot clears its gates

Add an architect review and approval trail; shared storage and access control; customer-approved knowledge retrieval with citations; versioned prompt and model evaluations; and integration only where permissions and audit needs are defined. Test a simpler non-AI intake template alongside the model to establish incremental value.
